1 **Cloud-based Building Information Modelling (CBIM): Software Engineers' Insights into** 2 **Improving Asset Information Quality**

3 4 **Abstract**

5
6 **Purpose:** This research investigates the capabilities of CBIM in managing quality asset
7 information, drawing upon software engineers' perspectives. Compelling statistics highlight the
8 relationship between building information and environmental sustainability. However, despite
9 the growing utilisation of CBIM in the Architecture, Engineering and Construction (AEC)
10 industry, a significant knowledge gap remains concerning its effectiveness in maintaining quality
11 asset information.

12
13 **Design/methodology/approach:** This study employed an exploratory qualitative approach,
14 utilising semi-structured interviews with thirteen software engineers actively developing
15 technological solutions for the AEC industry. Following thematic analysis, the findings are
16 categorised into four dimensions: strengths, weaknesses, opportunities, and technological
17 limitations. Subsequently, these findings are analysed in relation to previously identified
18 information quality problems.

19
20 **Findings:** This research reveals that while CBIM improves project coordination and information
21 accessibility, its effectiveness is challenged by the need for manual updates, vulnerability to
22 human errors, and dependency on network services. Technological limitations, notably the
23 absence of automated updates for as-built drawings and the risk of data loss during file
24 conversions in the design phase, coupled with its reduced capability to validate context-specific
25 information from the user's viewpoint, emphasise the urgent need for managerial strategies to
26 maximise CBIM's capabilities in addressing information quality problems.

27
28 **Originality/value:** This study augments the understanding of CBIM, highlighting the
29 managerial implications of a robust information management process to safeguard information
30 integrity. This approach fosters sustainable practices anchored in reliable information essential
31 for achieving desired outcomes. The findings also have broader managerial implications,
32 especially for sectors that employ CBIM as an instrumental tool.

7 36

8 37 **1. Introduction**

9
10 38 Buildings stand at the forefront of the global energy challenges. More than just structures,
11 39 they significantly contribute to energy consumption and carbon emissions, representing 40% of
12 40 global energy use and over 30% of worldwide CO₂ emissions, higher than the transportation and
13 41 industrial sectors (Kiamili *et al.*, 2020; Roberts *et al.*, 2018; Santos *et al.*, 2019). The United
14 42 States Department of Energy reports that approximately half of the energy used in buildings is
15 43 for heating and cooling. Addressing this issue, the World Green Building Council has set
16 44 ambitious targets: a 40% reduction in embodied and net-zero operational carbon by 2030,
17 45 progressing to net-zero carbon for the entire lifecycle of buildings by 2050 (Roberts *et al.*, 2020;
18 46 World Green Building Council, 2019). These goals are vital for building sustainable practices in
19 47 the building industry, as the environmental impact of today's construction choices will have
20 48 long-term consequences (Durdyev *et al.*, 2022).
21
22
23
24
25
26
27
28

29 49 In this context, quality asset information is integral to driving environmental sustainability
30 50 practices. Originally gathered at the handover phase of a building construction project, this
31 51 information provides essential asset information about the building (Pineiro, 2019). Initially
32 52 static, this information evolves dynamically in response to various projects throughout the
33 53 building's lifecycle, requiring adequate information management to be effective (Leygonie,
34 54 2020). Accurately updated asset information is indispensable for maintenance and operational
35 55 support while achieving the expected life of buildings (Chang *et al.*, 2022). This information is
36 56 intricately linked to environmental sustainability activities in buildings. Martins *et al.* (2019)
37 57 argue how asset information can mitigate environmental damage or, if managed inadequately,
38 58 intensify it. For example, poorly maintained equipment consumes more energy and emits more
39 59 harmful residues than well-maintained ones (Karpook and Meric, 2023). Given the complexity
40 60 of building systems and elements, Yalcinkaya and Vishal Singh (2014) underscore the growing
41 61 importance of dependable asset information as a key enabler for various environmental
42 62 sustainability initiatives.

1
2
3 65 BIM excels during the project delivery phase by creating a compressive suite of essential asset
4 66 details, spanning spatial zoning to individual components. Its capabilities include generating
5 67 extensive non-graphical information, such as error-reducing spreadsheets, through various
6 68 extensions and plugins (Pärn and Edwards, 2017). This wealth of information proves invaluable
7 69 in the use phase, including energy monitoring and sustainability management (Wong *et al.*,
8 70 2018). BIM's advanced data storage and ability to produce reliable, in-depth information mark it
9 71 as a key player in improving building operations. Matarneh *et al.* (2019a) highlight BIM's
10 72 emerging role, underscoring its transformative impact on building management and maintenance,
11 73 steering them toward enhancing sustainability.

12 74 BIM's ubiquitously quoted tangible benefits have recently been amplified by integrating
13 75 cloud-computing technologies. These advancements have shifted traditional desktop solutions to
14 76 the cloud, fostering greater collaboration and more efficient information flow during the design
15 77 phase. Despite these tangible benefits, the quality of asset information continues to pose a
16 78 persistent challenge, as Shalabi and Turkan (2017) noted. Moreover, manual data entry is
17 79 necessary for many building information management systems due to the lack of automated
18 80 information updates, leading to frequent human errors and omissions (Kumar and Lin, 2020). As
19 81 CBIM becomes prevalent in the building sector, a notable knowledge gap emerges regarding its
20 82 effectiveness in managing quality asset information during the use phase of buildings. This gap
21 83 leads us to the central research question:

22 84 ***To what extent can CBIM ensure the quality of asset information during the use phase of***
23 85 ***buildings?***

24 86 To address this research question, this study employs an exploratory approach to investigate
25 87 CBIM's information management capabilities from the software engineer's viewpoint. This
26 88 approach is unique yet important for uncovering the inherent technological limitation of CBIM
27 89 and understanding how to utilise this technological solution to enhance the quality of information
28 90 effectively. These insights are then cross-referenced with the existing information quality
29 91 problems, providing a fresh perspective on CBIM's effectiveness in managing quality
30 92 information. The results of this research enhance the current knowledge of CBIM and provide
31 93 practical and actionable contributions beyond the building sector.

32 94 The study is structured as follows: Section 2 reviews the extant literature on cloud
33 95 computing, BIM, CBIM and the concept of information quality. Section 3 outlines the

1
2
3 96 methodology used to assess CBIM's capabilities in information management through the lens of
4
5 97 software engineers. Section 4 presents the research findings. Section 5 discusses the key
6
7 98 findings, theoretical contributions, practical implications, limitations of this study and future
8
9 99 research directions based on the findings. Finally, Section 6 presents the conclusions drawn
10
11 100 from this research.

101 **2. Literature Review**

102 2.1. Cloud-based Building Information Modelling (CBIM)

103 Digital transformation has become an invaluable process for improving the productivity of
104 the AEC industry, which is highly fragmented and involves data-intensive processes across the
105 supply chain and lifecycle (Singh, 2019). BIM represents the modelling techniques used to
106 produce, communicate, analyse, and store information about buildings throughout their design,
107 construction, and serviceable life. Specifically, through access to accurate object-oriented
108 information at the correct time, BIM facilitates an integrated design and construction process,
109 resulting in high-quality buildings at lower costs and reduced project duration. It also supports
110 improved facility management (FM) and future refurbishment of buildings (Sacks *et al.*, 2018).
111 Serving as a shared knowledge source and storage, BIM can reduce the need for redundant data
112 collection and reformatting, leading to more efficient data storage and information exchange and
113 reduced costs associated with the lack of interoperability, automation of checking and analysis,
114 etc.

115 BIM enables modern construction projects to be complex and complicated, requiring
116 collaboration among various subcontractors for seamless data sharing throughout a project's
117 lifecycle (Alreshidi *et al.*, 2016; Ghaffarianhoseini *et al.*, 2017). Traditionally, desktop-based
118 BIM has faced challenges in maintaining model consistency and integrity, hindered by
119 coordination demands, interoperability issues among different software tools, and difficulties in
120 handling ongoing modifications and manual changes (Sacks *et al.*, 2022). Cloud computing
121 emerges as a solution, enabling on-demand delivery of configurable computing resources over
122 the Internet. This transition from desktop to server-based processing enhances the utilisation of
123 limited resources like computing power and storage. Integrating BIM with cloud computing
124 fosters efficient, cross-domain collaboration, ensuring a unified and consistent BIM model.
125 Additionally, it reduces the operational and maintenance costs of computing infrastructure. As
126 indicated by Zhao and Taib (2022) and other studies, CBIM will become the predominant

1
2
3 127 method, leveraging cloud computing's advantages. This evolution in BIM application promises
4
5 128 enhanced collaboration and efficiency in complex construction projects and safeguards the
6
7 129 quality of asset information.

8
9 130 Compared with conventional BIM, CBIM offers opportunities for improving cross-domain
10
11 131 and cross-organisation data storage, information exchange, and remote access, supporting
12
13 132 collaboration among multiple parties. Afsari *et al.* (2016) categorise three classifications of data
14
15 133 flow architectures used to enable the CBIM:

- 16 134 1. Manual transfer: This involves the labour-intensive transfer of vendor-neutral file-based
17
18 135 BIM (e.g., Industry Foundation Classes (IFC), IFC in short), which, despite being
19
20 136 cumbersome, is the most prevalent method for information exchange.
- 21 137 2. BIM server technology: This approach uses a single-source data server for data sharing
22
23 138 among project partners. Its limitation is the centralisation of BIM files on one server,
24
25 139 leading to potential bottlenecks and scalability issues.
- 26 140 3. Data interchange hub: this technology automates data flow between applications through
27
28 141 a hub, which synchronises data changes from different participants.

29
30
31 142 Various companies and academic institutions have developed CBIM solutions, such as Autodesk
32
33 143 BIM360, Trimble Connect, BIMserver, and Bentley i-Model (Wong *et al.*, 2014).

34 144 Table 1 shows the recent CBIM literature, highlighting their purpose, adopted BIM format,
35
36 145 data transmission process, and the addressed information quality problems. BIM data can be
37
38 146 represented, stored, and exchanged in different formats in collaborative BIM-based processes.
39
40 147 The IFC standard, a neutral data format, enhances BIM interoperability across platforms. Model
41
42 148 View Definitions (MVDs) also facilitate specific data exchange requirements between platforms.
43
44 149 An alternative approach utilises semantic web technology for representing building information,
45
46 150 such as spaces, assets, and construction processes. This approach offers flexibility in
47
48 151 representing and combining data from different domains into computer-readable graphs,
49
50 152 enabling efficient federation. In cloud-based data transmission, several protocols are used for
51
52 153 effective Internet exchange. These include the basic Transmission Control Protocol/Internet
53
54 154 Protocol (TCP/IP), Hypertext Transfer Protocol (HTTP) and File Transfer Protocol (FTP).
55
56 155 These protocols support a range of data formats, from complete IFC models to specific IFC
57
58 156 MVDs or BIM sub-graphs, varying in data size based on the application, software, and intended

157 use cases. The application perspective includes examining CBIM technologies that facilitate
158 collaboration, practices encouraging or hindering team collaboration, and data governance
159 strategies for secure and efficient data usage (Mutis and Mehraj, 2022).

160 **Table 1. The applications of CBIM and the addressed information quality problems.**

161 2.2. Information Quality

162 While BIM, whether desktop-based or cloud-enabled, has been proven as an efficient and
163 collaborative method for managing and storing information in project delivery and the use phase,
164 it is important to note that the technology itself does not automatically assure the quality of the
165 embedded information (Pärn *et al.*, 2016). Since essential building information predominately
166 originates from construction projects, the effective realisation of sustainability objectives through
167 BIM hinges critically on the quality of information fed into the system (Pinheiro, 2019).
168 Subsequently, the management of this information across the entire lifecycle of the physical
169 assets plays a pivotal role in ensuring the success of these sustainability goals.

170 Information quality is a complex and multi-dimensional concept without a universally
171 accepted set of dimensions and related definitions of each dimension (Wand and Wang, 1996;
172 Woodall *et al.*, 2013). The quality of information is assessed based on its ability to consistently
173 meet user expectations and requirements (e.g., sustainability), a subjective measure that varies by
174 context (Pringle *et al.*, 2002; Strong *et al.*, 1997; Wang and Strong, 1996). Effective information
175 management addresses this through the entire information lifecycle, including its creation,
176 organisation, storage, distribution, and use (DAMA International, 2017). Commonly cited
177 dimensions in literature are accuracy, completeness, consistency, and timeliness (Chang *et al.*,
178 2022; Woodall *et al.*, 2013):

- 179 • Accuracy: Information reflects the actual value.
- 180 • Completeness: All required information is present to meet the user's requirements.
- 181 • Consistency: The absence of difference when comparing multiple information.
- 182 • Timeliness: Information is sufficiently current for the task at hand.

183 Further elaborating on information quality problems, Ge and Helfert (2007), drawing from
184 previous studies, classified information quality issues into two categories: (1) context-
185 independent and context-dependent. Context-independent problems are those that occur
186 irrespective of the specific situation or application, including issues like spelling errors, data

187 omission, duplications, inconsistent formats, and incorrect values (Eppler, 2006; Oliveira *et al.*,
188 2005). Conversely, context-dependent problems are those that arise in response to specific
189 situational or contextual factors, with violation of company and government regulations serving
190 as a prime example (Pipino *et al.*, 2002). Additionally, the same authors evaluated these issues
191 from two distinctive lenses: the user perspective, which focuses on problems identified by
192 information consumers, and the data perspective, which addresses issues that are inherent to the
193 data itself, independent of any specific user's viewpoint (See Table 2).

194 **Table 2. Categorisation of information quality problems**

195 Leveraging the information quality problems listed in Table 2, this study explores CBIM's
196 contributions to preventing quality deterioration and ensuring the quality of asset information.

197 **3. Methodology**

198 This research argues that inductive theory generation on CBIM capabilities requires an in-
199 depth understanding of CBIM's inherent limitations through those who help develop this tool.
200 Therefore, this research employed a mono-method qualitative approach, leveraging semi-
201 structured interviews with software engineers. A sample of software engineers proficient in
202 developing technological solutions for the AEC industry was selected. This deliberate choice
203 facilitated an in-depth analysis of their unique viewpoints, providing technological capabilities
204 and efficiency of CBIM in handling quality asset information.

205 3.1. Sampling and recruitment

206 Using the purposive sampling technique described by (Lucas, 2014), this study engaged 13
207 participants from software solution providers in the US, UK, Finland and Germany. To ensure
208 that the sample represents the population, potential participants were required to develop
209 technological solutions for the AEC industry, with a specific focus on cloud technology. Table 3
210 details the profiles of the participants engaged in the interviews.

211 3.2. Data collection

212 Semi-structured interviews were chosen as the primary data collection method. Interviews
213 were more valuable than the survey in meeting the aim of this study because they allowed
214 participants to share experiences on the subject under investigation. Before the interviews, the
215 questions were systematically categorised into three main groups: (1) the advantages of
216 leveraging CBIM for effective information management, (2) the prevalent technological barriers
217 faced by CBIM, and (3) the ramifications of employing CBIM in the domain of asset information

1
2
3 218 management. Questions about the advantages of CBIM were instrumental in illuminating its
4 219 strengths and potential openings for innovation and improvement. Subsequently, questions
5 220 addressing technological challenges revealed the limitations intrinsic to CBIM, especially
6 221 concerning managing diverse asset information predominately rooted in current technological
7 222 constraints.

11 223 **Table 3. List of participants**

13 224 Participants had the option to skip questions deemed irrelevant or sensitive, particularly those
14 225 proving current product development specifics. Interviewing continued until data saturation was
15 226 reached, meaning no new information emerged from participants, as Easterby-Smith *et al.* (2021)
16 227 suggested. Interviews averaged 60 minutes. With prior consent, all interviews were recorded
17 228 and later transcribed for detailed analysis.

22 229 3.3. Data analysis

24 230 The data analysis followed the steps of thematic analysis recommended by Gioia *et al.*
25 231 (2013). Firstly, the interviews were coded using NVivo, a qualitative analysis software,
26 232 augmented by extensive notetaking to transform the raw data into 69 preliminary concepts. Each
27 233 researcher performed independent coding of the interviews reflecting the terminology used by
28 234 participants. Next, the researchers refined the coding scheme. Subsequently, the study
29 235 performed a data reduction process, eliminating redundant concepts, discarding categories
30 236 irrelevant to the research question, and merging categories into 16 second-order themes (Gioia *et al.*,
31 237 2013; Grodal *et al.*, 2021). The final cycle culminated in consolidating these themes into 4
32 238 broader dimensions: strengths, weaknesses, opportunities, and technical limitations.

39 239 To demonstrate the data analysis process, Figure 1 provides an example from an interview,
40 240 illustrating the steps involved in processing interview data. Initially considered raw data, the
41 241 interview transcript undergoes categorisation into ‘first-order concept’, which emerges as 69
42 242 categories from an analysis of 13 interviews. These first-order concepts are further refined into
43 243 ‘second-order themes’, such as ‘Innovation’, ‘Data Management’ and ‘Technology Constraints’,
44 244 totalling 16 themes. These second-order themes are then evaluated to identify ‘Strengths’,
45 245 ‘Weaknesses’, ‘Opportunities’, and ‘Technological Limitations’.

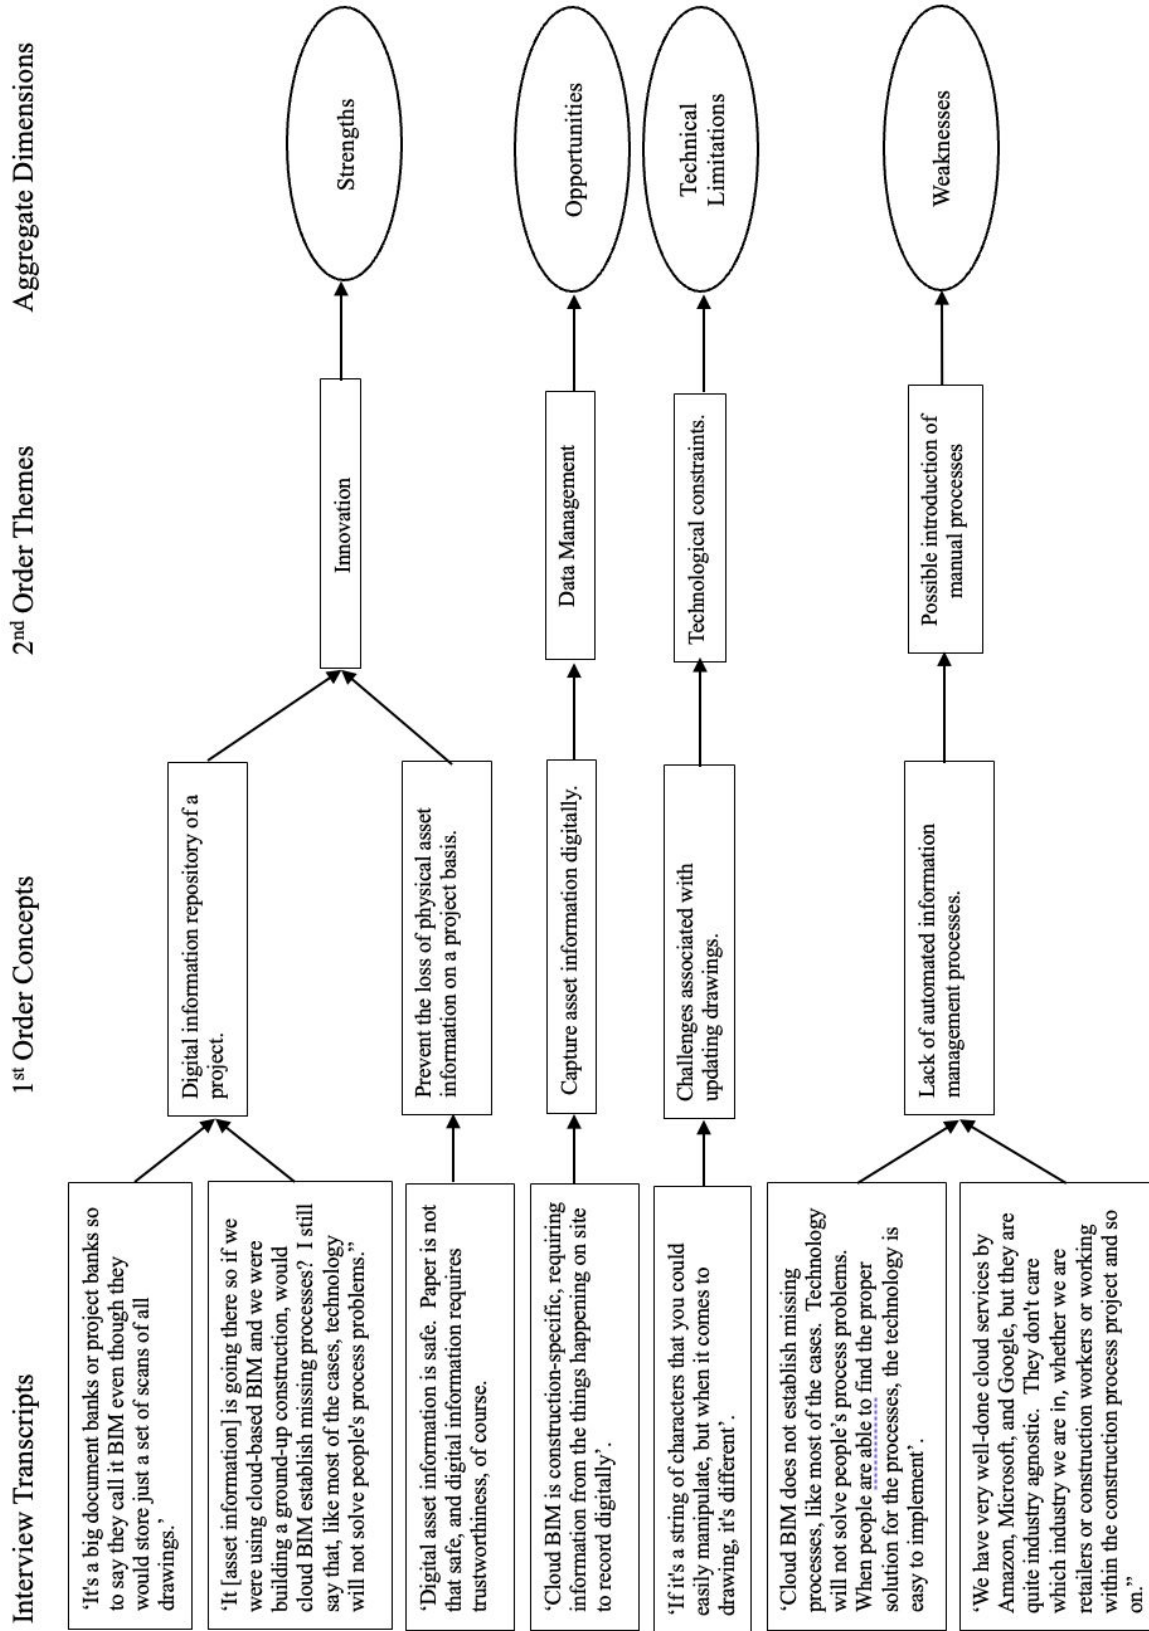

Figure 1. An example of thematic analysis of an interview

247 Significant insights were distilled from the raw data, transitioning software engineers’
 248 feedback into an interpretive analysis that enriches understanding of CBIM’s ability to manage
 249 quality asset information.

250 4. Results

251 This section presents CBIM's capabilities in managing quality asset information from the
 252 perspective of software engineers. Findings are derived from thematic analysis of interviews
 253 with anonymous coding (e.g., RQ3P1 and RQ3P2) to maintain confidentiality.

254 Adopting a SWOT (Strengths, Weaknesses, Opportunities, and Threats) analysis, findings
 255 are categorised into Strengths, Weaknesses, Opportunities, and Technological Limitations, with
 256 ‘Threats’ adapted to ‘Technological Limitations’ to better align with the focus of this study.
 257 Figure 2 illustrates the findings. Further, linking these findings with the information quality
 258 problems identified by Ge and Helfert (2007) are displayed in Figure 3.

259
 260 Figure 2. The capabilities of CBIM from software engineers’ viewpoint

261 4.1. Strengths

262 The participants have identified three compelling strengths of CBIM, underscoring its vital
 263 role in enhancing asset information quality within the building sector: (1) enhanced collaborative
 264 design phase, (2) robust digital storage, and (3) accessibility.

1
2
3 265 The participants indicate that CBIM enhances *'collaboration during the design phase'*,
4 266 leading to generating quality design in construction projects (RQ3P1). As RQ3P12 elucidated,
5 267 *'CBIM can orchestrate the multi-faceted information among the diverse project elements.'* The
6 268 collaboration among project participants streamlines workflows, while fostering cross-domain
7 269 collaboration to allow *'each [design element] is uniquely identified, and its details are accurately*
8 270 *represented in consistent manners'* (RQ3P3). This collaborative approach fosters the systematic
9 271 representation of asset information, tailoring the uniqueness of each asset while distinctly
10 272 expressing design details coherently (Liu *et al.*, 2020; Sacks *et al.*, 2022).

11 273 Another notable strength of CBIM as its innate ability for digital information storage, which
12 274 integrates *'naturally in the cloud-based environments'* (RQ3P4). In this context, CBIM adeptly
13 275 provides *'a single source of information containing multiple layers of mechanical, electrical, and*
14 276 *architectural information'* in contrast to traditional compilations of information (RQ3P1). This
15 277 system, acting as a robust repository for asset information, RQ3P2 underscored accessibility
16 278 offered by CBIM, stating, *'Cloud-based BIM enables us to find a vast amount of information*
17 279 *while providing easy access to those needs'* information. Moreover, *'When a new employee is*
18 280 *onboard, one can just sort through the CBIM to find the necessary information'* (RQ3P2).
19 281 Further, utilising CBIM as a centralised repository can reduce the risk associated with the loss of
20 282 tangible information, such as drawings.

21 283 4.2. Weaknesses

22 284 CBIM offers considerable benefits, yet it simultaneously introduces a set of challenges.
23 285 Participants have pinpointed key weaknesses: (1) an inability to define information management
24 286 processes, (2) human errors due to the reliance on manual processes, and (3) the dependency of
25 287 networks and servers. These shortcomings highlight managerial implications within the domain
26 288 of CBIM.

27 289 Although adopting technological solutions can enhance efficiency when using them
28 290 appropriately, they do not inherently establish an associated *'workflow'* (RQ3P7). Effective
29 291 workflows are the structural pillars of any organised process, vital for executing tasks efficiently
30 292 and uniformly. RQ3P2 notes that *'I feel strongly that technological solutions [software] do not*
31 293 *define the workflows.'* Without well-defined workflows, asset information management via
32 294 CBIM might not reach its full potential (RQ3P2). The lack of a methodical approach heightens
33 295 the risk of introducing errors and operational inefficiencies, undercutting the potential benefits of

1
2
3 296 the technology (RQ3P7). Consequently, while CBIM presents an opportunity to advance
4
5 297 operational efficiency, it is incumbent upon organisations to devise and implement bespoke,
6
7 298 robust workflows designed to align with and amplify the strengths of CBIM. As a result,
8
9 299 software engineers asserted the need for a robust '*internal information management procedure*'
10
11 300 to prevent the risk of information quality deterioration (RQ3P3, RQ3P5, RQ3P8, RQ3P11, &
12
13 301 RQ3P13).

14 302 Additionally, CBIM's reliance on manual updates jeopardises asset information quality. As
15
16 303 RQ3P7 indicates, '*All design elements are manually created during the design phase.*
17
18 304 *Consequently, the quality of these design elements is directly proportional to the designers'*
19
20 305 *expertise and attention to detail.*' Even during the use phase, CBIM depends on manual updates
21
22 306 of existing asset information corresponding to various building projects, which are prone to
23
24 307 '*human errors and oversights*' due to the lack of automated information update processes
25
26 308 (RQ3P3). This deficiency is especially pronounced in the upkeep of as-built drawings, which are
27
28 309 essential for accurate building representations as they guide various activities, including
29
30 310 maintenance, renovations, and physical space management. Continuous quality assurance
31
32 311 measures among project participants are necessary, requiring designers involved in each building
33
34 312 project to approve the quality of handover information before it is updated.

35
36 313 Finally, the dependency on networks and servers is recognised as an additional weakness of
37
38 314 CBIM. Continuous network connectivity emerges as a foundation for CBIM efficacy, where
39
40 315 disruptions can cripple system functionality, a situation that is particularly acute in regions with
41
42 316 inconsistent internet services (RQ3P8 and RQ3P10). Server dependency further compounds this
43
44 317 risk. Server outages can result in a complete loss of access to vital asset information, leading to
45
46 318 halted workflows and asset management activities. RQ3P12 also notes the critical risk of
47
48 319 information loss stemming from server crashes. These dependencies introduce substantial risks
49
50 320 of operational delays and inefficiencies. As such, there's a pressing need for CBIM to develop
51
52 321 resilient data management capabilities, including '*implementing redundant system*', '*crafting*
53
54 322 *offline functionality*' or '*exploring decentralised data storage solutions*' (RQ3P6, RQ3P7 and
55
56 323 RQ3P13).

57 324 4.3 Opportunities

58
59 325 RQ3P4, RQ3P9, and RQ3P10 collectively highlighted the transformative opportunity in
60
326 facilitating a 'drawing-less process' in the submittal procedures. The traditional submittal

1
2
3 327 process, characterised by a sequential approval mechanism required prior to fabrication
4
5 328 commencement, is undergoing transformative changes. *'For example, the contractor can submit*
6
7 329 *structural details, such as the I-beam and associated connector details, directly through CBIM*
8
9 330 *for the structural engineer's approval without generating hard copies of submittal drawings and*
10
11 331 *the associated material specifications. 'The accessibility of 3D models on laptops and tablets*
12
13 332 *has revolutionised the submittal process', as articulated by RQ3P4. Additionally, once*
14
15 333 submittals receive approval, they are readily available in an electronic format for fabrication
16
17 334 purposes. RQ3P10 further stated that *'this shift towards a drawing-less [object-based] process*
18
19 335 *is substantiated for national highway projects in the Nordic countries'*. This exemplifies the
20
21 336 opportunities and efficiencies offered by digital submittal processes in the building industry
22
23 337 facilitated by CBIM. It markedly reduces potential issues related to information quality and
24
25 338 guarantees the effective distribution of information across stakeholders.

26 339 4.4. Technological Limitations

27 340 Despite CBIM's innovative opportunities, software engineers pointed out technological
28
29 341 constraints in managing asset information quality: (1) a lack of an automated process of updating
30
31 342 as-built drawings and (2) information loss during the file conversion.

32 343 RQ3P1 elucidated, *'The concept of CBIM is using BIM software on cloud services, without*
33
34 344 *appropriate automated information flow processes. If it is a string of characters [non-graphical*
35
36 345 *information], you could easily manipulate to update the information using Excel, but when it*
37
38 346 *comes to drawings, it is different'. We currently do not have an automated process for updating*
39
40 347 *as-built drawings to reflect onsite modifications.'* To illustrate this point, non-graphical
41
42 348 information, such as the models, makers, and serial numbers of installed building components,
43
44 349 can be extracted into a tabular format, such as an Excel spreadsheet, to facilitate transferring
45
46 350 purposes. However, any modifications to the current as-built drawings require updates within
47
48 351 the original file format, such as a Revit model. Countering this perspective, RQ3P9 presents the
49
50 352 *'point cloud scanning technique'*. However, this method encounters limitations, including
51
52 353 extensive data processing time, scalability, and its restriction to capturing spatial information,
53
54 354 omitting essential details in enclosed areas, such as pipes behind walls or above ceilings.

55 355 In addition, RQ3P6 elaborated on inherent problems of information loss due to technological
56
57 356 constraints. This problem is exemplified in the process of *'converting a 3-dimensional model to*
58
59 357 *a 2-dimensional plan, where the conversion fails to transfer the embedded information within the*
60

1
2
3 358 *objects to the plan*', underscoring a significant challenge posed by technological constraints.
4
5 359 Typically, a 3D model is converted into 2D plans in AutoCAD format, which are widely utilised
6
7 360 for construction and space utilisation purposes. However, it is crucial to understand that while
8
9 361 dimensional modifications and configurational updates of 2D plans in AutoCAD format may
10
11 362 capture spatial alterations, they do not synchronise updates related to essential attributes, such as
12
13 363 wall types and thickness, in the corresponding 3D model. Delving this issue with a technical
14
15 364 lens, RQ3P3 illustrated a prevalent information issue of information loss through practical
16
17 365 applications: *'Using IFC, for example, we first map data from source X to IFC Y, and then when*
18
19 366 *reading data from IFC to application Z, we do another conversion. There are two opportunities*
20
21 367 *for information loss. Even if the information could be presented both in X and Z but not in the*
22
23 368 *intermediary format Y, the information is lost even though a direct link between X and Z could*
24
25 369 *perform the mapping*'. This explanation highlights the challenge of maintaining coherent and
26
27 370 up-to-date asset information across different model formats.

28 371 4.5. CBIM's capabilities to address information quality problems

29 372 This section provides an analysis of CBIM's effectiveness in addressing the quality issues
30
31 373 identified by Ge and Helfert (2007), as depicted in Figure 3. The analysis suggests that CBIM is
32
33 374 proficient in correcting context-independent data issues such as spelling and syntax errors. Yet,
34
35 375 its effectiveness is less assured when it comes to complex problems like the absence of necessary
36
37 376 data or incorrect values, indicating a need for improving data validation functions. From the
38
39 377 user's standpoint, CBIM is effective in providing access, retrieval, and secure storage of
40
41 378 information, facilitating fundamental user interactions. Nevertheless, it struggles with
42
43 379 transforming data into more user-friendly formats without compromising data integrity,
44
45 380 reflecting a crucial area for enhancement. These observations signal that while CBIM
46
47 381 competently addresses certain information quality issues, it requires further refinement to meet
48
49 382 the demands of context-independent information management and user experience.

50 383 Conversely, Figure 3 reveals that there were no specific information quality issues directly
51
52 384 attributable to CBIM from the context-dependent data perspective. However, it becomes evident
53
54 385 that CBIM is limited to resolving information quality problems to meet specific situations or user
55
56 386 requirements. This shortfall calls attention to the need to optimise resource distribution, analyse
57
58 387 business challenges, re-engineer processes, and re-align information flow from sources to
59
60 388 address problems effectively (Ge and Helfert, 2007).

389

390 Figure 3. A summary of CBIM's capabilities in asset information management

391

392 The SWOT analysis reveals various dimensions of CBIM's capabilities while highlighting its
 393 ability to validate context-dependent user perspective issues requires managerial oversight.

394 5. Discussion

395 This research has elucidated CBIM's capabilities in addressing information quality problems
 396 through the lens of software engineers developing technological solutions for the AEC industry.
 397 Understanding the intrinsic technological limitations is vital for optimising its potential in
 398 information management. Building on these insights, this section discusses contributions to
 399 theory and practice, acknowledges methodological limitations and provides suggestions for
 400 future studies.

401 5.1. Theoretical contribution

402 The theoretical contribution of this research lies in its deep exploration of the dynamic
 403 interplay between CBIM and asset information management, specifically addressing the complex
 404 challenges faced in preventing factors leading to the deterioration of handover information
 405 quality. This research acknowledges the capabilities of CBIM in enhancing collaborative design
 406 practices, a point underpinned by the findings of Sacks *et al.* (2022), yet it goes further to
 407 identify and theorise on the operational challenges, particularly the risk of information loss

1
2
3 408 during the design phase due to data conversion across disparate BIM software formats (Sacks *et*
4 409 *al.*, 2018). These operational challenges are not merely technical issues; they reflect deeper
5
6 410 systemic issues faced in the AEC industry, as argued by (Singh, 2019). For example, when
7
8 411 multiple BIM applications are involved, the incompatibility between data structures can lead to
9
10 412 significant information deterioration. This is not just a technological limitation of CBIM; it also
11
12 413 poses a substantial risk to the reliability of handover information, which is critical for the
13
14 414 operational integrity of physical assets (Matarneh *et al.*, 2022).

15 415 As such, this research proposes an ‘Integration Theory of CBIM and Asset Information
16 416 Management’, which advocates for a lifecycle-oriented approach to information quality. This
17 417 approach recognises the necessity of integrating CBIM practices within a broader asset
18 418 management strategy to align with the quality expectations of information users (Ge and Helfert,
19 419 2007). It advocates for context-specific processes that integrate CBIM, enabling automated
20 420 quality control mechanisms that utilise advanced analytics, machine learning, and artificial
21 421 intelligence to not only reactively identify but also proactively predict and mitigate potential
22 422 deterioration in information quality (Zabin *et al.*, 2022; Zhang, 2020). Moreover, the theory
23 423 introduces the concept of adaptive learning systems embedded within CBIM, which are designed
24 424 to refine information management practices by learning and evolving based on ongoing feedback
25 425 and information. This adaptability is crucial in a field characterised by constant change and
26 426 evolution, where asset information must be as dynamic and responsive as the environments in
27 427 which it is applied.

28 428 By proposing this theory, the research seeks to broaden the existing theoretical landscape of
29 429 asset information management to include elements specific to CBIM, such as the capacity for
30 430 real-time updates, the cultivation of collaborative environments beyond the design phase, and the
31 431 strategic use of digital twins to optimise the management of physical assets. The theory
32 432 positions CBIM not as a mere repository or static tool but as a dynamic facilitator of asset
33 433 management, potentially bringing about significant enhancements in the efficiency of asset
34 434 management, sustainability, and adaptability. In envisioning a holistic integration of CBIM
35 435 within asset management, this research sets forth a theoretical framework that aims to provoke a
36 436 paradigm shift toward more efficient and sustainable practices in the built environment. This
37 437 paradigm shift requires overcoming significant challenges, including ensuring interoperability

1
2
3 438 across diverse BIM tools, developing predictive analytics for quality control, and fostering an
4
5 439 industry-wide acceptance of these advanced methodologies.

6 440 5.2. Practical relevance

7
8 441 Grounded in the ‘Integration Theory of CBIM and Asset Information Management’, this
9
10 442 theory advocates for a lifecycle-centric approach underpinned by continuous adaptation and
11
12 443 feedback mechanisms. These mechanisms are essential for enhancing asset information quality
13
14 444 through CBIM. A practical application of this theory is developing an advanced collaborative
15
16 445 platform designed to support CBIM activities. From the perspective of technological solution
17
18 446 providers, this innovation facilitates using cloud-based storage to support multiple products from
19
20 447 the same company, eliminating the need to transfer project data from one solution to another.
21
22 448 Such an approach reduces errors caused by human intervention and the potential loss of
23
24 449 information during the file import and export processes. Simultaneously, this model enables
25
26 450 end-users to leverage analytics for various asset management activities, fostering informed
27
28 451 decision-making underpinned by quality asset information. This paradigm shift propels asset
29
30 452 management from traditional, static practices to dynamic, feedback-driven processes that are
31
32 453 emblematic of adaptive learning principles.

33
34 454 Moreover, managing as-built drawings can benefit from incorporating automated quality
35
36 455 control mechanisms that resonate with the proposed theoretical insights. Innovations such as
37
38 456 CBIM plugins utilising emerging scanning techniques to automate updates to as-built drawings
39
40 457 are pivotal. They can mirror real-time modifications, aiming to minimise manual processing for
41
42 458 drawing updates, reduce human errors, and ensure the quality of as-built drawings.

43
44 459 Further, overcoming challenges related to internet connectivity, especially in less developed
45
46 460 or rural areas, involves harnessing the capabilities of digital twin technologies. This approach is
47
48 461 bolstered by advancements in 5G technology and the anticipation of 6G networks. It aligns with
49
50 462 the theory’s advocacy for real-time updates and collaborative environments, illustrating the
51
52 463 practical application of theoretical concepts into tangible, actionable strategies. Integrating
53
54 464 digital twins with CBIM optimises the asset management process, rendering it more efficient,
55
56 465 sustainable, and adaptable to the evolving dynamics of the built environment.

57
58 466 Embedding these practical recommendations presents a visionary strategy for employing
59
60 467 CBIM in asset management. It illustrates how theoretical insights can catalyse significant
468
469 practice transformation, establishing a new standard for efficiency, sustainability, and

1
2
3 469 adaptability in the built environment. Beyond the AEC industry, sectors such as civil
4 470 engineering, infrastructure, transportation, aviation, manufacturing, real estate, urban planning,
5 471 and smart city initiatives stand to benefit from these recommendations. Implementing these
6 472 recommendations promotes an environment where the potential of CBIM can be fully realised,
7 473 facilitating various activities with quality asset information.

11 474 5.3. Limitations and suggestions for future research

13 475 The exploration of CBIM in the AEC industry, primarily from software engineers'
14 476 perspectives, presents vital insights into its capabilities and limitations within asset information
15 477 management. However, this concentration limits the exploration to a singular viewpoint,
16 478 potentially missing the broader spectrum of challenges and opportunities perceived by the end
17 479 users, such as asset management professionals. While rich in detail, this research's qualitative
18 480 nature constrains the conclusions' scalability and generalisability. Notably, the technical hurdles
19 481 highlighted, including information loss during file conversions and the absence of automated
20 482 updates for as-built drawings, underscore the need for technological advancements and highlight
21 483 the complexity of implementing CBIM in real-world scenarios.

22 484 Future research into CBIM must broaden to include diverse stakeholder perspectives,
23 485 including end-users and regulatory bodies, enhancing insights into CBIM's utility during the use
24 486 phase of buildings. Integrating quantitative methodologies, such as surveys and case studies,
25 487 will complement existing qualitative insights, offering a detailed view of the effects of CBIM on
26 488 asset information quality and operational efficiency. Addressing technological advancement is
27 489 critical, focusing on developing algorithms and machine learning techniques for automating
28 490 information updates and minimising information loss during file conversions. This technological
29 491 push should be accompanied by efforts to enhance software interoperability, ensuring consistent
30 492 information quality throughout the asset's lifecycle. Moreover, constructing comprehensive
31 493 frameworks for CBIM implementation and conducting longitudinal studies will be vital. This
32 494 framework should incorporate best practices for information management and stakeholder
33 495 collaboration, while longitudinal studies could reveal CBIM's long-term sustainability and
34 496 economic benefits, providing a holistic view of its potential enhancement and efficiency.

35 497 **6. Conclusions**

36 498 This study critically evaluated the application of CBIM in the building sector, focusing on its
37 499 capabilities in managing information quality, as perceived by software engineers. Key findings

1
2
3 500 of this research indicate that while CBIM can address context-independent quality problems such
4
5 501 as spelling errors and digital storage, it requires additional managerial oversights and strategic
6
7 502 operational adjustments to exploit its potential fully. A comparative review of these findings
8
9 503 with existing literature reveals that although adopting CBIM is widespread in the AEC industry,
10
11 504 the focus largely remains on technological advancements rather than on its integration into
12
13 505 broader information management processes, a discrepancy that highlights a significant area for
14
15 506 future research. This study extends the current understanding of CBIM's capabilities by
16
17 507 highlighting the necessity for continuous quality assurance and adopting advanced technological
18
19 508 strategies to overcome CBIM's limitations. Moreover, it emphasises the importance of refining
20
21 509 CBIM integration strategies and procedural optimisations to address these challenges effectively.
22
23 510 Therefore, strategic management and continuous improvement are crucial to address its
24
25 511 operational vulnerabilities and maximise its capabilities to improve handover information
26
27 512 quality.

1 **Cloud-based Building Information Modelling (CBIM): Software Engineers' Insights into** 2 **Improving Asset Information Quality**

3 4 **Abstract**

5
6 **Purpose:** This research investigates the capabilities of CBIM in managing quality asset
7 information, drawing upon software engineers' perspectives. Compelling statistics highlight the
8 relationship between building information and environmental sustainability. However, despite
9 the growing utilisation of CBIM in the Architecture, Engineering and Construction (AEC)
10 industry, a significant knowledge gap remains concerning its effectiveness in maintaining quality
11 asset information.
12

13 **Design/methodology/approach:** This study employed an exploratory qualitative approach,
14 utilising semi-structured interviews with thirteen software engineers actively developing
15 technological solutions for the AEC industry. Following thematic analysis, the findings are
16 categorised into four dimensions: strengths, weaknesses, opportunities, and technological
17 limitations. Subsequently, these findings are analysed in relation to previously identified
18 information quality problems.
19

20 **Findings:** This research reveals that while CBIM improves project coordination and information
21 accessibility, its effectiveness is challenged by the need for manual updates, vulnerability to
22 human errors, and dependency on network services. Technological limitations, notably the
23 absence of automated updates for as-built drawings and the risk of data loss during file
24 conversions in the design phase, coupled with its reduced capability to validate context-specific
25 information from the user's viewpoint, emphasise the urgent need for managerial strategies to
26 maximise CBIM's capabilities in addressing information quality problems.
27

28 **Originality/value:** This study augments the understanding of CBIM, highlighting the
29 managerial implications of a robust information management process to safeguard information
30 integrity. This approach fosters sustainable practices anchored in reliable information essential
31 for achieving desired outcomes. The findings also have broader managerial implications,
32 especially for sectors that employ CBIM as an instrumental tool.

7 36

8 37 **1. Introduction**

9
10 38 Buildings stand at the forefront of the global energy challenges. More than just structures,
11 39 they significantly contribute to energy consumption and carbon emissions, representing 40% of
12 40 global energy use and over 30% of worldwide CO₂ emissions, higher than the transportation and
13 41 industrial sectors (Kiamili *et al.*, 2020; Roberts *et al.*, 2018; Santos *et al.*, 2019). The United
14 42 States Department of Energy reports that approximately half of the energy used in buildings is
15 43 for heating and cooling. Addressing this issue, the World Green Building Council has set
16 44 ambitious targets: a 40% reduction in embodied and net-zero operational carbon by 2030,
17 45 progressing to net-zero carbon for the entire lifecycle of buildings by 2050 (Roberts *et al.*, 2020;
18 46 World Green Building Council, 2019). These goals are vital for building sustainable practices in
19 47 the building industry, as the environmental impact of today's construction choices will have
20 48 long-term consequences (Durdyev *et al.*, 2022).
21
22
23
24
25
26
27
28

29 49 In this context, quality asset information is integral to driving environmental sustainability
30 50 practices. Originally gathered at the handover phase of a building construction project, this
31 51 information provides essential asset information about the building (Pineiro, 2019). Initially
32 52 static, this information evolves dynamically in response to various projects throughout the
33 53 building's lifecycle, requiring adequate information management to be effective (Leygonie,
34 54 2020). Accurately updated asset information is indispensable for maintenance and operational
35 55 support while achieving the expected life of buildings (Chang *et al.*, 2022). This information is
36 56 intricately linked to environmental sustainability activities in buildings. Martins *et al.* (2019)
37 57 argue how asset information can mitigate environmental damage or, if managed inadequately,
38 58 intensify it. For example, poorly maintained equipment consumes more energy and emits more
39 59 harmful residues than well-maintained ones (Karpook and Meric, 2023). Given the complexity
40 60 of building systems and elements, Yalcinkaya and Vishal Singh (2014) underscore the growing
41 61 importance of dependable asset information as a key enabler for various environmental
42 62 sustainability initiatives.
43
44
45
46
47
48
49
50
51
52

53 63 From an information management perspective, the growing adoption of Building Information
54 64 Modelling (BIM) holds significant potential for augmenting the quality of asset information.
55
56
57
58
59
60

1
2
3 65 BIM excels during the project delivery phase by creating a compressive suite of essential asset
4 66 details, spanning spatial zoning to individual components. Its capabilities include generating
5 67 extensive non-graphical information, such as error-reducing spreadsheets, through various
6 68 extensions and plugins (Pärn and Edwards, 2017). This wealth of information proves invaluable
7 69 in the use phase, including energy monitoring and sustainability management (Wong *et al.*,
8 70 2018). BIM's advanced data storage and ability to produce reliable, in-depth information mark it
9 71 as a key player in improving building operations. Matarneh *et al.* (2019a) highlight BIM's
10 72 emerging role, underscoring its transformative impact on building management and maintenance,
11 73 steering them toward enhancing sustainability.

12 74 BIM's ubiquitously quoted tangible benefits have recently been amplified by integrating
13 75 cloud-computing technologies. These advancements have shifted traditional desktop solutions to
14 76 the cloud, fostering greater collaboration and more efficient information flow during the design
15 77 phase. Despite these tangible benefits, the quality of asset information continues to pose a
16 78 persistent challenge, as Shalabi and Turkan (2017) noted. Moreover, manual data entry is
17 79 necessary for many building information management systems due to the lack of automated
18 80 information updates, leading to frequent human errors and omissions (Kumar and Lin, 2020). As
19 81 CBIM becomes prevalent in the building sector, a notable knowledge gap emerges regarding its
20 82 effectiveness in managing quality asset information during the use phase of buildings. This gap
21 83 leads us to the central research question:

22 84 ***To what extent can CBIM ensure the quality of asset information during the use phase of***
23 85 ***buildings?***

24 86 To address this research question, this study employs an exploratory approach to investigate
25 87 CBIM's information management capabilities from the software engineer's viewpoint. This
26 88 approach is unique yet important for uncovering the inherent technological limitation of CBIM
27 89 and understanding how to utilise this technological solution to enhance the quality of information
28 90 effectively. These insights are then cross-referenced with the existing information quality
29 91 problems, providing a fresh perspective on CBIM's effectiveness in managing quality
30 92 information. The results of this research enhance the current knowledge of CBIM and provide
31 93 practical and actionable contributions beyond the building sector.

32 94 The study is structured as follows: Section 2 reviews the extant literature on cloud
33 95 computing, BIM, CBIM and the concept of information quality. Section 3 outlines the

1
2
3 96 methodology used to assess CBIM's capabilities in information management through the lens of
4
5 97 software engineers. Section 4 presents the research findings. Section 5 discusses the key
6
7 98 findings, theoretical contributions, practical implications, limitations of this study and future
8
9 99 research directions based on the findings. Finally, Section 6 presents the conclusions drawn
10
11 100 from this research.

101 **2. Literature Review**

102 2.1. Cloud-based Building Information Modelling (CBIM)

103 Digital transformation has become an invaluable process for improving the productivity of
104 the AEC industry, which is highly fragmented and involves data-intensive processes across the
105 supply chain and lifecycle (Singh, 2019). BIM represents the modelling techniques used to
106 produce, communicate, analyse, and store information about buildings throughout their design,
107 construction, and serviceable life. Specifically, through access to accurate object-oriented
108 information at the correct time, BIM facilitates an integrated design and construction process,
109 resulting in high-quality buildings at lower costs and reduced project duration. It also supports
110 improved facility management (FM) and future refurbishment of buildings (Sacks *et al.*, 2018).
111 Serving as a shared knowledge source and storage, BIM can reduce the need for redundant data
112 collection and reformatting, leading to more efficient data storage and information exchange and
113 reduced costs associated with the lack of interoperability, automation of checking and analysis,
114 etc.

115 BIM enables modern construction projects to be complex and complicated, requiring
116 collaboration among various subcontractors for seamless data sharing throughout a project's
117 lifecycle (Alreshidi *et al.*, 2016; Ghaffarianhoseini *et al.*, 2017). Traditionally, desktop-based
118 BIM has faced challenges in maintaining model consistency and integrity, hindered by
119 coordination demands, interoperability issues among different software tools, and difficulties in
120 handling ongoing modifications and manual changes (Sacks *et al.*, 2022). Cloud computing
121 emerges as a solution, enabling on-demand delivery of configurable computing resources over
122 the Internet. This transition from desktop to server-based processing enhances the utilisation of
123 limited resources like computing power and storage. Integrating BIM with cloud computing
124 fosters efficient, cross-domain collaboration, ensuring a unified and consistent BIM model.
125 Additionally, it reduces the operational and maintenance costs of computing infrastructure. As
126 indicated by Zhao and Taib (2022) and other studies, CBIM will become the predominant

1
2
3 127 method, leveraging cloud computing's advantages. This evolution in BIM application promises
4 128 enhanced collaboration and efficiency in complex construction projects and safeguards the
5 129 quality of asset information.

6
7
8
9 130 Compared with conventional BIM, CBIM offers opportunities for improving cross-domain
10 131 and cross-organisation data storage, information exchange, and remote access, supporting
11 132 collaboration among multiple parties. Afsari *et al.* (2016) categorise three classifications of data
12 133 flow architectures used to enable the CBIM:

- 13 134 1. Manual transfer: This involves the labour-intensive transfer of vendor-neutral file-based
14 135 BIM (e.g., Industry Foundation Classes (IFC), IFC in short), which, despite being
15 136 cumbersome, is the most prevalent method for information exchange.
- 16 137 2. BIM server technology: This approach uses a single-source data server for data sharing
17 138 among project partners. Its limitation is the centralisation of BIM files on one server,
18 139 leading to potential bottlenecks and scalability issues.
- 19 140 3. Data interchange hub: this technology automates data flow between applications through
20 141 a hub, which synchronises data changes from different participants.

21
22
23 142 Various companies and academic institutions have developed CBIM solutions, such as Autodesk
24 143 BIM360, Trimble Connect, BIMserver, and Bentley i-Model (Wong *et al.*, 2014).

25 144 Table 1 shows the recent CBIM literature, highlighting their purpose, adopted BIM format,
26 145 data transmission process, and the addressed information quality problems. BIM data can be
27 146 represented, stored, and exchanged in different formats in collaborative BIM-based processes.
28 147 The IFC standard, a neutral data format, enhances BIM interoperability across platforms. Model
29 148 View Definitions (MVDs) also facilitate specific data exchange requirements between platforms.
30 149 An alternative approach utilises semantic web technology for representing building information,
31 150 such as spaces, assets, and construction processes. This approach offers flexibility in
32 151 representing and combining data from different domains into computer-readable graphs,
33 152 enabling efficient federation. In cloud-based data transmission, several protocols are used for
34 153 effective Internet exchange. These include the basic Transmission Control Protocol/Internet
35 154 Protocol (TCP/IP), Hypertext Transfer Protocol (HTTP) and File Transfer Protocol (FTP).
36 155 These protocols support a range of data formats, from complete IFC models to specific IFC
37 156 MVDs or BIM sub-graphs, varying in data size based on the application, software, and intended

157 use cases. The application perspective includes examining CBIM technologies that facilitate
158 collaboration, practices encouraging or hindering team collaboration, and data governance
159 strategies for secure and efficient data usage (Mutis and Mehraj, 2022).

160 **Table 1. The applications of CBIM and the addressed information quality problems.**

161 2.2. Information Quality

162 While BIM, whether desktop-based or cloud-enabled, has been proven as an efficient and
163 collaborative method for managing and storing information in project delivery and the use phase,
164 it is important to note that the technology itself does not automatically assure the quality of the
165 embedded information (Pärn *et al.*, 2016). Since essential building information predominately
166 originates from construction projects, the effective realisation of sustainability objectives through
167 BIM hinges critically on the quality of information fed into the system (Pineiro, 2019).
168 Subsequently, the management of this information across the entire lifecycle of the physical
169 assets plays a pivotal role in ensuring the success of these sustainability goals.

170 Information quality is a complex and multi-dimensional concept without a universally
171 accepted set of dimensions and related definitions of each dimension (Wand and Wang, 1996;
172 Woodall *et al.*, 2013). The quality of information is assessed based on its ability to consistently
173 meet user expectations and requirements (e.g., sustainability), a subjective measure that varies by
174 context (Pringle *et al.*, 2002; Strong *et al.*, 1997; Wang and Strong, 1996). Effective information
175 management addresses this through the entire information lifecycle, including its creation,
176 organisation, storage, distribution, and use (DAMA International, 2017). Commonly cited
177 dimensions in literature are accuracy, completeness, consistency, and timeliness (Chang *et al.*,
178 2022; Woodall *et al.*, 2013):

- 179 • Accuracy: Information reflects the actual value.
- 180 • Completeness: All required information is present to meet the user's requirements.
- 181 • Consistency: The absence of difference when comparing multiple information.
- 182 • Timeliness: Information is sufficiently current for the task at hand.

183 Further elaborating on information quality problems, Ge and Helfert (2007), drawing from
184 previous studies, classified information quality issues into two categories: (1) context-
185 independent and context-dependent. Context-independent problems are those that occur
186 irrespective of the specific situation or application, including issues like spelling errors, data

187 omission, duplications, inconsistent formats, and incorrect values (Eppler, 2006; Oliveira *et al.*,
188 2005). Conversely, context-dependent problems are those that arise in response to specific
189 situational or contextual factors, with violation of company and government regulations serving
190 as a prime example (Pipino *et al.*, 2002). Additionally, the same authors evaluated these issues
191 from two distinctive lenses: the user perspective, which focuses on problems identified by
192 information consumers, and the data perspective, which addresses issues that are inherent to the
193 data itself, independent of any specific user's viewpoint (See Table 2).

194 **Table 2. Categorisation of information quality problems**

195 Leveraging the information quality problems listed in Table 2, this study explores CBIM's
196 contributions to preventing quality deterioration and ensuring the quality of asset information.

197 **3. Methodology**

198 This research argues that inductive theory generation on CBIM capabilities requires an in-
199 depth understanding of CBIM's inherent limitations through those who help develop this tool.
200 Therefore, this research employed a mono-method qualitative approach, leveraging semi-
201 structured interviews with software engineers. A sample of software engineers proficient in
202 developing technological solutions for the AEC industry was selected. This deliberate choice
203 facilitated an in-depth analysis of their unique viewpoints, providing technological capabilities
204 and efficiency of CBIM in handling quality asset information.

205 3.1. Sampling and recruitment

206 Using the purposive sampling technique described by (Lucas, 2014), this study engaged 13
207 participants from software solution providers in the US, UK, Finland and Germany. To ensure
208 that the sample represents the population, potential participants were required to develop
209 technological solutions for the AEC industry, with a specific focus on cloud technology. Table 3
210 details the profiles of the participants engaged in the interviews.

211 3.2. Data collection

212 Semi-structured interviews were chosen as the primary data collection method. Interviews
213 were more valuable than the survey in meeting the aim of this study because they allowed
214 participants to share experiences on the subject under investigation. Before the interviews, the
215 questions were systematically categorised into three main groups: (1) the advantages of
216 leveraging CBIM for effective information management, (2) the prevalent technological barriers
217 faced by CBIM, and (3) the ramifications of employing CBIM in the domain of asset information

1
2
3 218 management. Questions about the advantages of CBIM were instrumental in illuminating its
4 219 strengths and potential openings for innovation and improvement. Subsequently, questions
5 220 addressing technological challenges revealed the limitations intrinsic to CBIM, especially
6 221 concerning managing diverse asset information predominately rooted in current technological
7 222 constraints.

11 223 **Table 3. List of participants**

13 224 Participants had the option to skip questions deemed irrelevant or sensitive, particularly those
14 225 proving current product development specifics. Interviewing continued until data saturation was
15 226 reached, meaning no new information emerged from participants, as Easterby-Smith *et al.* (2021)
16 227 suggested. Interviews averaged 60 minutes. With prior consent, all interviews were recorded
17 228 and later transcribed for detailed analysis.

22 229 3.3. Data analysis

24 230 The data analysis followed the steps of thematic analysis recommended by Gioia *et al.*
25 231 (2013). Firstly, the interviews were coded using NVivo, a qualitative analysis software,
26 232 augmented by extensive notetaking to transform the raw data into 69 preliminary concepts. Each
27 233 researcher performed independent coding of the interviews reflecting the terminology used by
28 234 participants. Next, the researchers refined the coding scheme. Subsequently, the study
29 235 performed a data reduction process, eliminating redundant concepts, discarding categories
30 236 irrelevant to the research question, and merging categories into 16 second-order themes (Gioia *et al.*,
31 237 2013; Grodal *et al.*, 2021). The final cycle culminated in consolidating these themes into 4
32 238 broader dimensions: strengths, weaknesses, opportunities, and technical limitations.

39 239 To demonstrate the data analysis process, Figure 1 provides an example from an interview,
40 240 illustrating the steps involved in processing interview data. Initially considered raw data, the
41 241 interview transcript undergoes categorisation into ‘first-order concept’, which emerges as 69
42 242 categories from an analysis of 13 interviews. These first-order concepts are further refined into
43 243 ‘second-order themes’, such as ‘Innovation’, ‘Data Management’ and ‘Technology Constraints’,
44 244 totalling 16 themes. These second-order themes are then evaluated to identify ‘Strengths’,
45 245 ‘Weaknesses’, ‘Opportunities’, and ‘Technological Limitations’.

2nd Order Themes

1st Order Concepts

Interview Transcripts

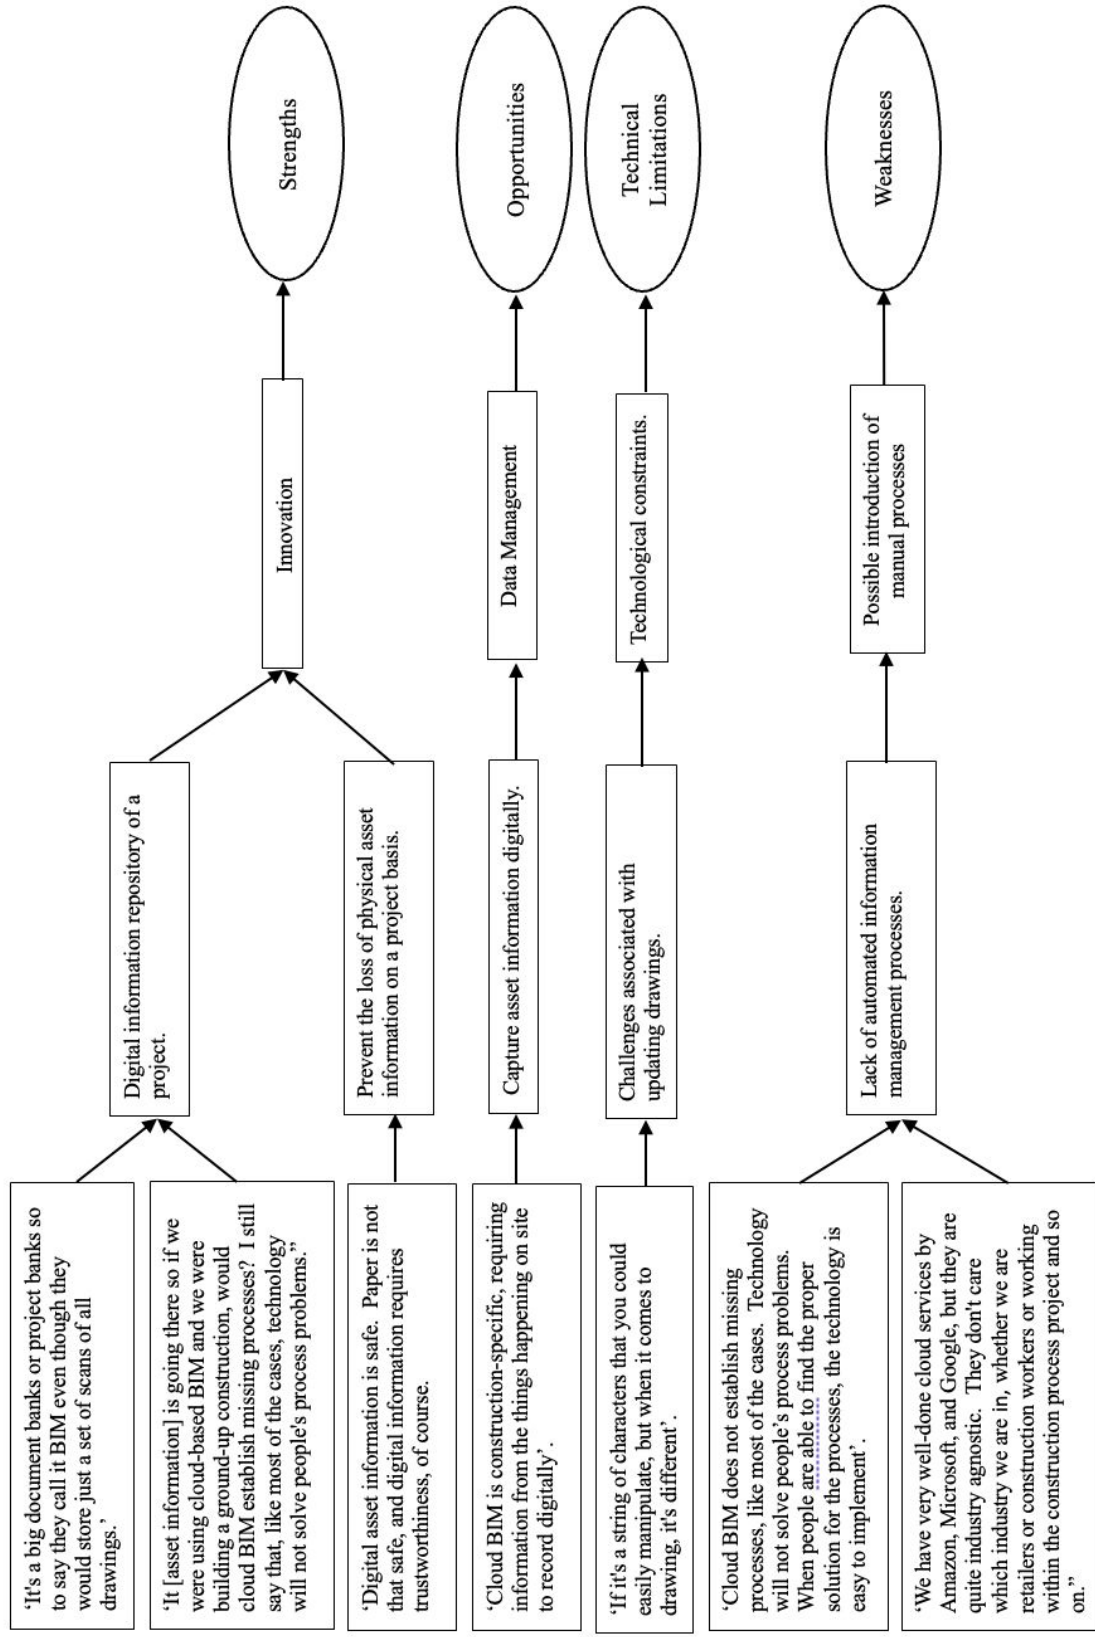

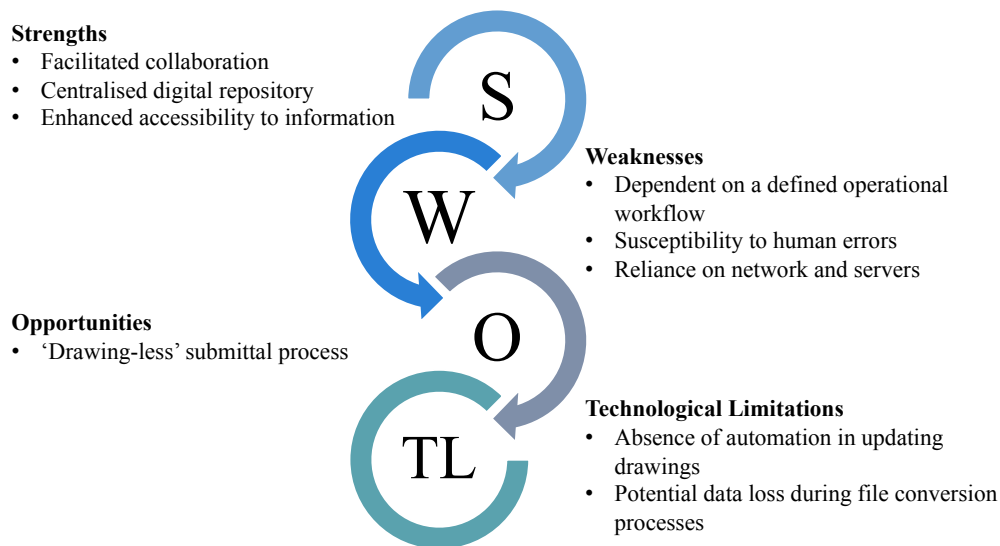

Figure 1. An example of thematic analysis of an interview

247 Significant insights were distilled from the raw data, transitioning software engineers’
 248 feedback into an interpretive analysis that enriches understanding of CBIM’s ability to manage
 249 quality asset information.

250 4. Results

251 This section presents CBIM's capabilities in managing quality asset information from the
 252 perspective of software engineers. Findings are derived from thematic analysis of interviews
 253 with anonymous coding (e.g., RQ3P1 and RQ3P2) to maintain confidentiality.

254 Adopting a SWOT (Strengths, Weaknesses, Opportunities, and Threats) analysis, findings
 255 are categorised into Strengths, Weaknesses, Opportunities, and Technological Limitations, with
 256 ‘Threats’ adapted to ‘Technological Limitations’ to better align with the focus of this study.
 257 Figure 2 illustrates the findings. Further, linking these findings with the information quality
 258 problems identified by Ge and Helfert (2007) are displayed in Figure 3.

259
 260 Figure 2. The capabilities of CBIM from software engineers’ viewpoint

261 4.1. Strengths

262 The participants have identified three compelling strengths of CBIM, underscoring its vital
 263 role in enhancing asset information quality within the building sector: (1) enhanced collaborative
 264 design phase, (2) robust digital storage, and (3) accessibility.

1
2
3 265 The participants indicate that CBIM enhances *'collaboration during the design phase'*,
4 266 leading to generating quality design in construction projects (RQ3P1). As RQ3P12 elucidated,
5 267 *'CBIM can orchestrate the multi-faceted information among the diverse project elements.'* The
6 268 collaboration among project participants streamlines workflows, while fostering cross-domain
7 269 collaboration to allow *'each [design element] is uniquely identified, and its details are accurately*
8 270 *represented in consistent manners'* (RQ3P3). This collaborative approach fosters the systematic
9 271 representation of asset information, tailoring the uniqueness of each asset while distinctly
10 272 expressing design details coherently (Liu *et al.*, 2020; Sacks *et al.*, 2022).

11 273 Another notable strength of CBIM as its innate ability for digital information storage, which
12 274 integrates *'naturally in the cloud-based environments'* (RQ3P4). In this context, CBIM adeptly
13 275 provides *'a single source of information containing multiple layers of mechanical, electrical, and*
14 276 *architectural information'* in contrast to traditional compilations of information (RQ3P1). This
15 277 system, acting as a robust repository for asset information, RQ3P2 underscored accessibility
16 278 offered by CBIM, stating, *'Cloud-based BIM enables us to find a vast amount of information*
17 279 *while providing easy access to those needs'* information. Moreover, *'When a new employee is*
18 280 *onboard, one can just sort through the CBIM to find the necessary information'* (RQ3P2).
19 281 Further, utilising CBIM as a centralised repository can reduce the risk associated with the loss of
20 282 tangible information, such as drawings.

21 283 4.2. Weaknesses

22 284 CBIM offers considerable benefits, yet it simultaneously introduces a set of challenges.
23 285 Participants have pinpointed key weaknesses: (1) an inability to define information management
24 286 processes, (2) human errors due to the reliance on manual processes, and (3) the dependency of
25 287 networks and servers. These shortcomings highlight managerial implications within the domain
26 288 of CBIM.

27 289 Although adopting technological solutions can enhance efficiency when using them
28 290 appropriately, they do not inherently establish an associated *'workflow'* (RQ3P7). Effective
29 291 workflows are the structural pillars of any organised process, vital for executing tasks efficiently
30 292 and uniformly. RQ3P2 notes that *'I feel strongly that technological solutions [software] do not*
31 293 *define the workflows.'* Without well-defined workflows, asset information management via
32 294 CBIM might not reach its full potential (RQ3P2). The lack of a methodical approach heightens
33 295 the risk of introducing errors and operational inefficiencies, undercutting the potential benefits of

1
2
3 296 the technology (RQ3P7). Consequently, while CBIM presents an opportunity to advance
4
5 297 operational efficiency, it is incumbent upon organisations to devise and implement bespoke,
6
7 298 robust workflows designed to align with and amplify the strengths of CBIM. As a result,
8
9 299 software engineers asserted the need for a robust *'internal information management procedure'*
10
11 300 to prevent the risk of information quality deterioration (RQ3P3, RQ3P5, RQ3P8, RQ3P11, &
12
13 301 RQ3P13).

14 302 Additionally, CBIM's reliance on manual updates jeopardises asset information quality. As
15
16 303 RQ3P7 indicates, *'All design elements are manually created during the design phase.*
17
18 304 *Consequently, the quality of these design elements is directly proportional to the designers'*
19
20 305 *expertise and attention to detail.'* Even during the use phase, CBIM depends on manual updates
21
22 306 of existing asset information corresponding to various building projects, which are prone to
23
24 307 *'human errors and oversights'* due to the lack of automated information update processes
25
26 308 (RQ3P3). This deficiency is especially pronounced in the upkeep of as-built drawings, which are
27
28 309 essential for accurate building representations as they guide various activities, including
29
30 310 maintenance, renovations, and physical space management. Continuous quality assurance
31
32 311 measures among project participants are necessary, requiring designers involved in each building
33
34 312 project to approve the quality of handover information before it is updated.

35
36 313 Finally, the dependency on networks and servers is recognised as an additional weakness of
37
38 314 CBIM. Continuous network connectivity emerges as a foundation for CBIM efficacy, where
39
40 315 disruptions can cripple system functionality, a situation that is particularly acute in regions with
41
42 316 inconsistent internet services (RQ3P8 and RQ3P10). Server dependency further compounds this
43
44 317 risk. Server outages can result in a complete loss of access to vital asset information, leading to
45
46 318 halted workflows and asset management activities. RQ3P12 also notes the critical risk of
47
48 319 information loss stemming from server crashes. These dependencies introduce substantial risks
49
50 320 of operational delays and inefficiencies. As such, there's a pressing need for CBIM to develop
51
52 321 resilient data management capabilities, including *'implementing redundant system'*, *'crafting*
53
54 322 *offline functionality'* or *'exploring decentralised data storage solutions'* (RQ3P6, RQ3P7 and
55
56 323 RQ3P13).

57 324 4.3 Opportunities

58
59 325 RQ3P4, RQ3P9, and RQ3P10 collectively highlighted the transformative opportunity in
60
326 facilitating a 'drawing-less process' in the submittal procedures. The traditional submittal

1
2
3 327 process, characterised by a sequential approval mechanism required prior to fabrication
4
5 328 commencement, is undergoing transformative changes. *'For example, the contractor can submit*
6
7 329 *structural details, such as the I-beam and associated connector details, directly through CBIM*
8
9 330 *for the structural engineer's approval without generating hard copies of submittal drawings and*
10
11 331 *the associated material specifications. 'The accessibility of 3D models on laptops and tablets*
12
13 332 *has revolutionised the submittal process', as articulated by RQ3P4. Additionally, once*
14
15 333 submittals receive approval, they are readily available in an electronic format for fabrication
16
17 334 purposes. RQ3P10 further stated that *'this shift towards a drawing-less [object-based] process*
18
19 335 *is substantiated for national highway projects in the Nordic countries'*. This exemplifies the
20
21 336 opportunities and efficiencies offered by digital submittal processes in the building industry
22
23 337 facilitated by CBIM. It markedly reduces potential issues related to information quality and
24
25 338 guarantees the effective distribution of information across stakeholders.

26 339 4.4. Technological Limitations

27 340 Despite CBIM's innovative opportunities, software engineers pointed out technological
28
29 341 constraints in managing asset information quality: (1) a lack of an automated process of updating
30
31 342 as-built drawings and (2) information loss during the file conversion.

32 343 RQ3P1 elucidated, *'The concept of CBIM is using BIM software on cloud services, without*
33
34 344 *appropriate automated information flow processes. If it is a string of characters [non-graphical*
35
36 345 *information], you could easily manipulate to update the information using Excel, but when it*
37
38 346 *comes to drawings, it is different'. We currently do not have an automated process for updating*
39
40 347 *as-built drawings to reflect onsite modifications.'* To illustrate this point, non-graphical
41
42 348 information, such as the models, makers, and serial numbers of installed building components,
43
44 349 can be extracted into a tabular format, such as an Excel spreadsheet, to facilitate transferring
45
46 350 purposes. However, any modifications to the current as-built drawings require updates within
47
48 351 the original file format, such as a Revit model. Countering this perspective, RQ3P9 presents the
49
50 352 *'point cloud scanning technique'*. However, this method encounters limitations, including
51
52 353 extensive data processing time, scalability, and its restriction to capturing spatial information,
53
54 354 omitting essential details in enclosed areas, such as pipes behind walls or above ceilings.

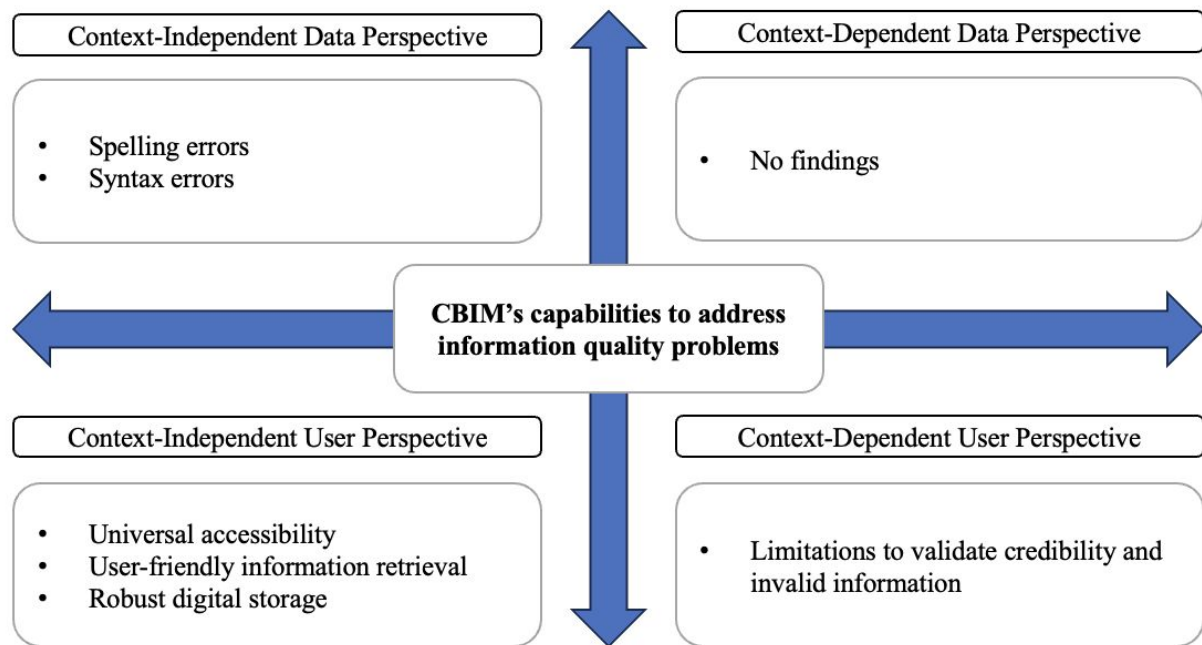

55 355 In addition, RQ3P6 elaborated on inherent problems of information loss due to technological
56
57 356 constraints. This problem is exemplified in the process of *'converting a 3-dimensional model to*
58
59 357 *a 2-dimensional plan, where the conversion fails to transfer the embedded information within the*
60

1
2
3 358 *objects to the plan*', underscoring a significant challenge posed by technological constraints.
4
5 359 Typically, a 3D model is converted into 2D plans in AutoCAD format, which are widely utilised
6
7 360 for construction and space utilisation purposes. However, it is crucial to understand that while
8
9 361 dimensional modifications and configurational updates of 2D plans in AutoCAD format may
10
11 362 capture spatial alterations, they do not synchronise updates related to essential attributes, such as
12
13 363 wall types and thickness, in the corresponding 3D model. Delving this issue with a technical
14
15 364 lens, RQ3P3 illustrated a prevalent information issue of information loss through practical
16
17 365 applications: *'Using IFC, for example, we first map data from source X to IFC Y, and then when*
18
19 366 *reading data from IFC to application Z, we do another conversion. There are two opportunities*
20
21 367 *for information loss. Even if the information could be presented both in X and Z but not in the*
22
23 368 *intermediary format Y, the information is lost even though a direct link between X and Z could*
24
25 369 *perform the mapping*'. This explanation highlights the challenge of maintaining coherent and
26
27 370 up-to-date asset information across different model formats.

28 371 4.5. CBIM's capabilities to address information quality problems

29 372 This section provides an analysis of CBIM's effectiveness in addressing the quality issues
30
31 373 identified by Ge and Helfert (2007), as depicted in Figure 3. The analysis suggests that CBIM is
32
33 374 proficient in correcting context-independent data issues such as spelling and syntax errors. Yet,
34
35 375 its effectiveness is less assured when it comes to complex problems like the absence of necessary
36
37 376 data or incorrect values, indicating a need for improving data validation functions. From the
38
39 377 user's standpoint, CBIM is effective in providing access, retrieval, and secure storage of
40
41 378 information, facilitating fundamental user interactions. Nevertheless, it struggles with
42
43 379 transforming data into more user-friendly formats without compromising data integrity,
44
45 380 reflecting a crucial area for enhancement. These observations signal that while CBIM
46
47 381 competently addresses certain information quality issues, it requires further refinement to meet
48
49 382 the demands of context-independent information management and user experience.

50 383 Conversely, Figure 3 reveals that there were no specific information quality issues directly
51
52 384 attributable to CBIM from the context-dependent data perspective. However, it becomes evident
53
54 385 that CBIM is limited to resolving information quality problems to meet specific situations or user
55
56 386 requirements. This shortfall calls attention to the need to optimise resource distribution, analyse
57
58 387 business challenges, re-engineer processes, and re-align information flow from sources to
59
60 388 address problems effectively (Ge and Helfert, 2007).

389

390 Figure 3. A summary of CBIM's capabilities in asset information management

391

392 The SWOT analysis reveals various dimensions of CBIM's capabilities while highlighting its
 393 ability to validate context-dependent user perspective issues requires managerial oversight.

394 5. Discussion

395 This research has elucidated CBIM's capabilities in addressing information quality problems
 396 through the lens of software engineers developing technological solutions for the AEC industry.

397 Understanding the intrinsic technological limitations is vital for optimising its potential in
 398 information management. Building on these insights, this section discusses contributions to
 399 theory and practice, acknowledges methodological limitations and provides suggestions for
 400 future studies.

401 5.1. Key findings

402 ~~—The synthesis of findings from the literature review and the interviews with software
 403 engineers reveals a multifaceted view of CBIM's role in enhancing handover information
 404 quality. While the literature emphasises CBIM's contribution to mitigating quality issues during
 405 the design phase, the interview results caution against over-dependence due to tangible
 406 limitations, advocating for a balanced approach to CBIM's technological potential and practical
 407 challenges. Consequently, targeted efforts in technological refinements and procedural~~

~~optimisations are necessary to address these issues. Despite challenges, CBIM is pivotal in facilitating efficient information exchange and enhancing project data quality. Strategic management and continuous improvement are crucial to address its operational vulnerabilities and maximise its capabilities to improve handover information quality.~~

5.12. Theoretical contribution

The theoretical contribution of this research lies in its deep exploration of the dynamic interplay between CBIM and asset information management, specifically addressing the complex challenges faced in preventing factors leading to the deterioration of handover information quality. This research acknowledges the capabilities of CBIM in enhancing collaborative design practices, a point underpinned by the findings of Sacks *et al.* (2022), yet it goes further to identify and theorise on the operational challenges, particularly the risk of information loss during the design phase due to data conversion across disparate BIM software formats (Sacks *et al.*, 2018). These operational challenges are not merely technical issues; they reflect deeper systemic issues faced in the AEC industry, as argued by (Singh, 2019). For example, when multiple BIM applications are involved, the incompatibility between data structures can lead to significant information deterioration. This is not just a technological limitation of CBIM; it also poses a substantial risk to the reliability of handover information, which is critical for the operational integrity of physical assets (Matarneh *et al.*, 2022).

As such, this research proposes an ‘Integration Theory of CBIM and Asset Information Management’, which advocates for a lifecycle-oriented approach to information quality. This approach recognises the necessity of integrating CBIM practices within a broader asset management strategy to align with the quality expectations of information users (Ge and Helfert, 2007). It advocates for context-specific processes that integrate CBIM, enabling ~~calls for developing and deploying~~ automated quality control mechanisms that utilise advanced analytics, machine learning, and artificial intelligence to not only reactively identify but also proactively predict and mitigate potential deterioration in information quality (Zabin *et al.*, 2022; Zhang, 2020). Moreover, the theory introduces the concept of adaptive learning systems embedded within CBIM, which are designed to refine information management practices by learning and evolving based on ongoing feedback and information. This adaptability is crucial in a field characterised by constant change and evolution, where asset information must be as dynamic and responsive as the environments in which it is applied.

1
2
3 439 By proposing this theory, the research seeks to broaden the existing theoretical landscape of
4 440 asset information management to include elements specific to CBIM, such as the capacity for
5
6 441 real-time updates, the cultivation of collaborative environments beyond the design phase, and the
7
8 442 strategic use of digital twins to optimise the management of physical assets. The theory
9
10 443 positions CBIM not as a mere repository or static tool but as a dynamic facilitator of asset
11
12 444 management, potentially bringing about significant enhancements in the efficiency of asset
13
14 445 management, sustainability, and adaptability. In envisioning a holistic integration of CBIM
15
16 446 within asset management, this research sets forth a theoretical framework that aims to provoke a
17
18 447 paradigm shift toward more efficient and sustainable practices in the built environment. This
19
20 448 paradigm shift requires overcoming significant challenges, including ensuring interoperability
21
22 449 across diverse BIM tools, developing predictive analytics for quality control, and fostering an
23
24 450 industry-wide acceptance of these advanced methodologies.

24 451 5.23. Practical relevance

25
26 452 Grounded in the 'Integration Theory of CBIM and Asset Information Management', this
27
28 453 theory advocates for a lifecycle-centric approach underpinned by continuous adaptation and
29
30 454 feedback mechanisms. These mechanisms are essential for enhancing asset information quality
31
32 455 through CBIM. A practical application of this theory is developing an advanced collaborative
33
34 456 platform designed to support CBIM activities. From the perspective of technological solution
35
36 457 providers, this innovation facilitates using cloud-based storage to support multiple products from
37
38 458 the same company, eliminating the need to transfer project data from one solution to another.
39
40 459 Such an approach reduces errors caused by human intervention and the potential loss of
41
42 460 information during the file import and export processes. Simultaneously, this model enables
43
44 461 end-users to leverage analytics for various asset management activities, fostering informed
45
46 462 decision-making underpinned by quality asset information. This paradigm shift propels asset
47
48 463 management from traditional, static practices to dynamic, feedback-driven processes that are
49
50 464 emblematic of adaptive learning principles.

51
52 465 Moreover, managing as-built drawings can benefit from incorporating automated quality
53
54 466 control mechanisms that resonate with the proposed theoretical insights. Innovations such as
55
56 467 CBIM plugins utilising emerging scanning techniques to automate updates to as-built drawings
57
58 468 are pivotal. They can mirror real-time modifications, aiming to minimise manual processing for
59
60 469 drawing updates, reduce human errors, and ensure the quality of as-built drawings.

1
2
3 470 Further, overcoming challenges related to internet connectivity, especially in less developed
4
5 471 or rural areas, involves harnessing the capabilities of digital twin technologies. This approach is
6
7 472 bolstered by advancements in 5G technology and the anticipation of 6G networks. It aligns with
8
9 473 the theory's advocacy for real-time updates and collaborative environments, illustrating the
10
11 474 practical application of theoretical concepts into tangible, actionable strategies. Integrating
12
13 475 digital twins with CBIM optimises the asset management process, rendering it more efficient,
14
15 476 sustainable, and adaptable to the evolving dynamics of the built environment.

16
17 477 Embedding these practical recommendations presents a visionary strategy for employing
18
19 478 CBIM in asset management. It illustrates how theoretical insights can catalyse significant
20
21 479 practice transformation, establishing a new standard for efficiency, sustainability, and
22
23 480 adaptability in the built environment. Beyond the AEC industry, sectors such as civil
24
25 481 engineering, infrastructure, transportation, aviation, manufacturing, real estate, urban planning,
26
27 482 and smart city initiatives stand to benefit from these recommendations. Implementing these
28
29 483 recommendations promotes an environment where the potential of CBIM can be fully realised,
30
31 484 facilitating various activities with quality asset information.

32 485 5.34. Limitations and suggestions for future research

33
34 486 The exploration of CBIM in the AEC industry, primarily from software engineers'
35
36 487 perspectives, presents vital insights into its capabilities and limitations within asset information
37
38 488 management. However, this concentration limits the exploration to a singular viewpoint,
39
40 489 potentially missing the broader spectrum of challenges and opportunities perceived by the end
41
42 490 users, such as asset management professionals. While rich in detail, this research's qualitative
43
44 491 nature constrains the conclusions' scalability and generalisability. Notably, the technical hurdles
45
46 492 highlighted, including information loss during file conversions and the absence of automated
47
48 493 updates for as-built drawings, underscore the need for technological advancements and highlight
49
50 494 the complexity of implementing CBIM in real-world scenarios.

51
52 495 Future research into CBIM must broaden to include diverse stakeholder perspectives,
53
54 496 including end-users and regulatory bodies, enhancing insights into CBIM's utility during the use
55
56 497 phase of buildings. Integrating quantitative methodologies, such as surveys and case studies,
57
58 498 will complement existing qualitative insights, offering a detailed view of the effects of CBIM on
59
60 499 asset information quality and operational efficiency. Addressing technological advancement is
500
501 500 critical, focusing on developing algorithms and machine learning techniques for automating

1
2
3 501 information updates and minimising information loss during file conversions. This technological
4
5 502 push should be accompanied by efforts to enhance software interoperability, ensuring consistent
6
7 503 information quality throughout the asset's lifecycle. Moreover, constructing comprehensive
8
9 504 frameworks for CBIM implementation and conducting longitudinal studies will be vital. This
10
11 505 framework should incorporate best practices for information management and stakeholder
12
13 506 collaboration, while longitudinal studies could reveal CBIM's long-term sustainability and
14
15 507 economic benefits, providing a holistic view of its potential enhancement and efficiency.

16 508 **6. Conclusions**

17 509 This study critically evaluated the application of CBIM in the building sector, focusing on its
18
19 510 capabilities in managing information quality, as perceived by software engineers. Key findings
20
21 511 of this research indicate that while CBIM can address context-independent quality problems such
22
23 512 as spelling errors and digital storage, it requires additional managerial oversights and strategic
24
25 513 operational adjustments to exploit its potential fully. A comparative review of these findings
26
27 514 with existing literature reveals that although adopting CBIM is widespread in the AEC industry,
28
29 515 the focus largely remains on technological advancements rather than on its integration into
30
31 516 broader information management processes, a discrepancy that highlights a significant area for
32
33 517 future research. This study extends the current understanding of CBIM's capabilities by
34
35 518 highlighting the necessity for continuous quality assurance and adopting advanced technological
36
37 519 strategies to overcome CBIM's limitations. Moreover, it emphasises the importance of refining
38
39 520 CBIM integration strategies and procedural optimisations to address these challenges effectively.
40
41 521 Therefore, strategic management and continuous improvement are crucial to address its
42
43 522 operational vulnerabilities and maximise its capabilities to improve handover information
44
45 523 quality. Recognising the prevalence of CBIM in the building sector, this study identified CBIM's
46
47 524 capabilities in managing quality through the lens of software engineers to understand the
48
49 525 technological boundaries that might limit its application. Despite its benefits, CBIM encounters
50
51 526 several challenges that require managerial oversights and innovative operational strategies to
52
53 527 harness its full potential. Addressing these challenges, this research underscores the importance
54
55 528 of continuous quality assurance and the utilisation of technological advancement to overcome
56
57 529 CBIM's existing limitations. Further research is crucial to maximise CBIM's contribution to
58
59 530 optimising asset information quality and enhancing efficiency and sustainable practices in the
60
61 531 built environment.

1 Response to reviewers' comments to BEPAM-12-2023-0247

2 Please use the **BEPAM-12-2023-0247.R2_Final_no track change_06232024** document to reference line numbers.

4 Dear Drs Rodrigo, Sridarran & Reviewers,

5 We are grateful that you have given us an opportunity to refine the manuscript. Your constructive feedback has undoubtedly improved the quality of
6 our work. Thank you again for considering our work.

9 Reviewer 1

Item	Categories	Reviewer's comment	Corresponding line numbers	Response
1		The authors have addressed all comments. However, I'd suggest linking the outcomes of this paper back to existing literature (currently there is only one - Sacks et.al).	BEPAM-12-2023-0247.R2_Final_no track change_06232024 Lines 408 – 409, Line 410, Lines 416 – 419, Line 419, and Line 422.	We link the outcomes of this research to the following literature: Lines 408 – 409 (Sacks et al., 2018) Line 410 as argued by (Singh, 2019) Line 414 (Matarneh <i>et al.</i> , 2022) Lines 416 – 419 This approach recognises the necessity of integrating CBIM practices within a broader asset management strategy to align with the quality expectations of information users (Ge and Helfert, 2007). Line 419 It advocates for context-specific processes that integrate CBIM Line 422 (Zabin <i>et al.</i> , 2022; Zhang, 2020)

				Please see the updated text in the revised manuscript.

Guest Editor' Comments

1A	Summary of key findings in Conclusion	Please provide a summary of key findings in Conclusions.	BEPAM-12-2023-0247.R2_Final_no track change_06232024 Line 401, Line 440, Line 474	We eliminated Section 5.1 Key findings to conclusion. Due to this change, we updated the numbering of the subsections in the discussion sections: Line 401 5.1. Theoretical contribution Line 440 5.2. Practical relevance Line 474 5.3. Limitations and suggestions for future research
1B	Conclusion	As implications to theory and practice as well as limitations and future research directions have been moved to Discussion, the conclusion does not look strong. Therefore, I would recommend to expand the discussion session a little bit by comparing your findings with existing literature. Afterwards move implications to theory and practice, limitations and future research directions, to Conclusions section.	BEPAM-12-2023-0247.R2_Final_no track change_06232024 Lines 498 - 512	We revised the conclusion including key findings of this research: This study critically evaluated the application of CBIM in the building sector, focusing on its capabilities in managing information quality, as perceived by software engineers. Key findings of this research indicate that while CBIM can address context-independent quality problems such as spelling errors and digital storage, it requires additional managerial oversights and strategic operational adjustments to exploit its potential fully. A comparative review of these findings with existing literature reveals that although adopting CBIM is widespread in the AEC industry, the focus largely remains on technological advancements rather than on its integration into broader information management processes, a discrepancy

				<p>that highlights a significant area for future research. This study extends the current understanding of CBIM’s capabilities by highlighting the necessity for continuous quality assurance and adopting advanced technological strategies to overcome CBIM’s limitations. Moreover, it emphasises the importance of refining CBIM integration strategies and procedural optimisations to address these challenges effectively. Therefore, strategic management and continuous improvement are crucial to address its operational vulnerabilities and maximise its capabilities to improve handover information quality.</p>
--	--	--	--	--

Table 1. The applications of CBIM and the addressed information quality problems.

Purpose	BIM format	Data transmission	Reference	Addressed Information quality problems
Facilitate collaborative design in the construction projects by ensuring model consistency and object-level version control.	RDF graphs from IFC files	Not specified, but transfer BIM sub-graphs for explicit federated	Sacks <i>et al.</i> (2022)	Design accuracy, consistency, and completeness.
Enable facility management users to retrieve and transfer various data sources seamlessly into facility management systems.	IFC files parsed into a relational database (Microsoft SQL Server)	Cloud SQL server	Matarneh <i>et al.</i> (2022)	Improved data accessibility and accuracy in facility management systems
Foster digital collaboration among stakeholders for generating the projects' Green Mark score, meeting regulatory standards.	IFC2x3	Custom cloud platform, as a common data environment for the Green Mark scheme	Liu <i>et al.</i> (2020)	Design accuracy and regulatory compliance.
Introduce a system for real-time BIM-VR synchronization system, updating VR headsets with BIM changes instantly.	Autodesk Revit	Customised cloud server and database	Du <i>et al.</i> (2018)	Accuracy and timeliness of the information.
Provide a web-based service for viewing, storing, and analysing extensive building information models.	MapReduce for IFC files, saved in cloud database	Apache Hadoop with Bigtable-like storage on distributed servers	Chen <i>et al.</i> (2016)	Centralised information repository to minimise information loss, ensuring accuracy, and accessibility.
Enhance communication efficiency among project participants to improve design quality and reduce rework.	Entire or partial IFC building models	Amazon Elastic Compute Cloud (EC2) hosting BIM information within NoSQL databases	Das <i>et al.</i> (2015)	Design accuracy, consistency, completeness and timeliness.
Facilitate timely information access for monitoring progress and managing the construction of a reinforced concrete (RC) structure	Autodesk Revit	Autodesk BIM 360	Matthews <i>et al.</i> (2015)	Accuracy, completeness, and timeliness to update RC construction progress.

Table 2. Categorisation of information quality problems, adapted from Ge and Helfert (2007).

	Context-independent	Context-dependent
Data perspective	<ul style="list-style-type: none"> • Errors in spelling. • Absence of necessary data. • Incorrect value. • Repetition of data. • Data formats that are not uniform. • Syntax errors. • Violation of integrity rules. • Diverse units of measurement. • Presence of synonyms and homonyms 	<ul style="list-style-type: none"> • Breach of domain constraints. • Infringement of the organisation's business rules. • Non-compliance with company and government regulations. • Violation of constraints provided by the database administrator.
User perspective	<ul style="list-style-type: none"> • Access to information is unattainable. • Information is insecure. • Retrieving information is challenging. • Compiling information poses considerable difficulties. • Transforming information is prone to inaccuracies. 	<ul style="list-style-type: none"> • The information lacks factual grounding. • The credibility of the information is questionable. • The information offers a biased perspective. • The information bears no relevance to the task at hand. • The information is not comprehensive. • The information is presented in a condensed format. • The information is challenging to alter or use. • The information is difficult to comprehend. • The information is no longer current.

Table 3. List of participants

Participant ID	Job title	Experience (years)	Types of organisations	Location
RQ3P1	Data Enterprises	17	Industrial technology solutions	US
RQ3P2	Vice President, Digital Solutions	25	Industrial technology solutions	US
RQ3P3	Director Digital Products	32	Industrial technology solutions	US
RQ3P4	Distinguished Software Engineer	25	Industrial technology solutions	US
RQ3P5	Vice President, Design Solutions	27	Industrial technology solutions	US
RQ3P6	Co-Founder of Digital Products	20	Applications & software developer	UK
RQ3P7	Software Engineer/Consultant	15	Industrial Technology Solutions/Digital Consulting	UK
RQ3P8	Senior Software Engineer	19	Industrial technology solutions	Finland
RQ3P9	Distinguished Software Engineer	33	Industrial technology solutions	Finland
RQ3P10	Software Engineer	5	Industrial technology solutions	Finland
RQ3P11	Software Engineer	18	Industrial technology solutions	Finland
RQ3P12	Software Engineer	5	Industrial technology solutions	Germany
RQ3P13	Chief Executive Officer	18	Industrial technology solutions/Digital Consulting	Germany
